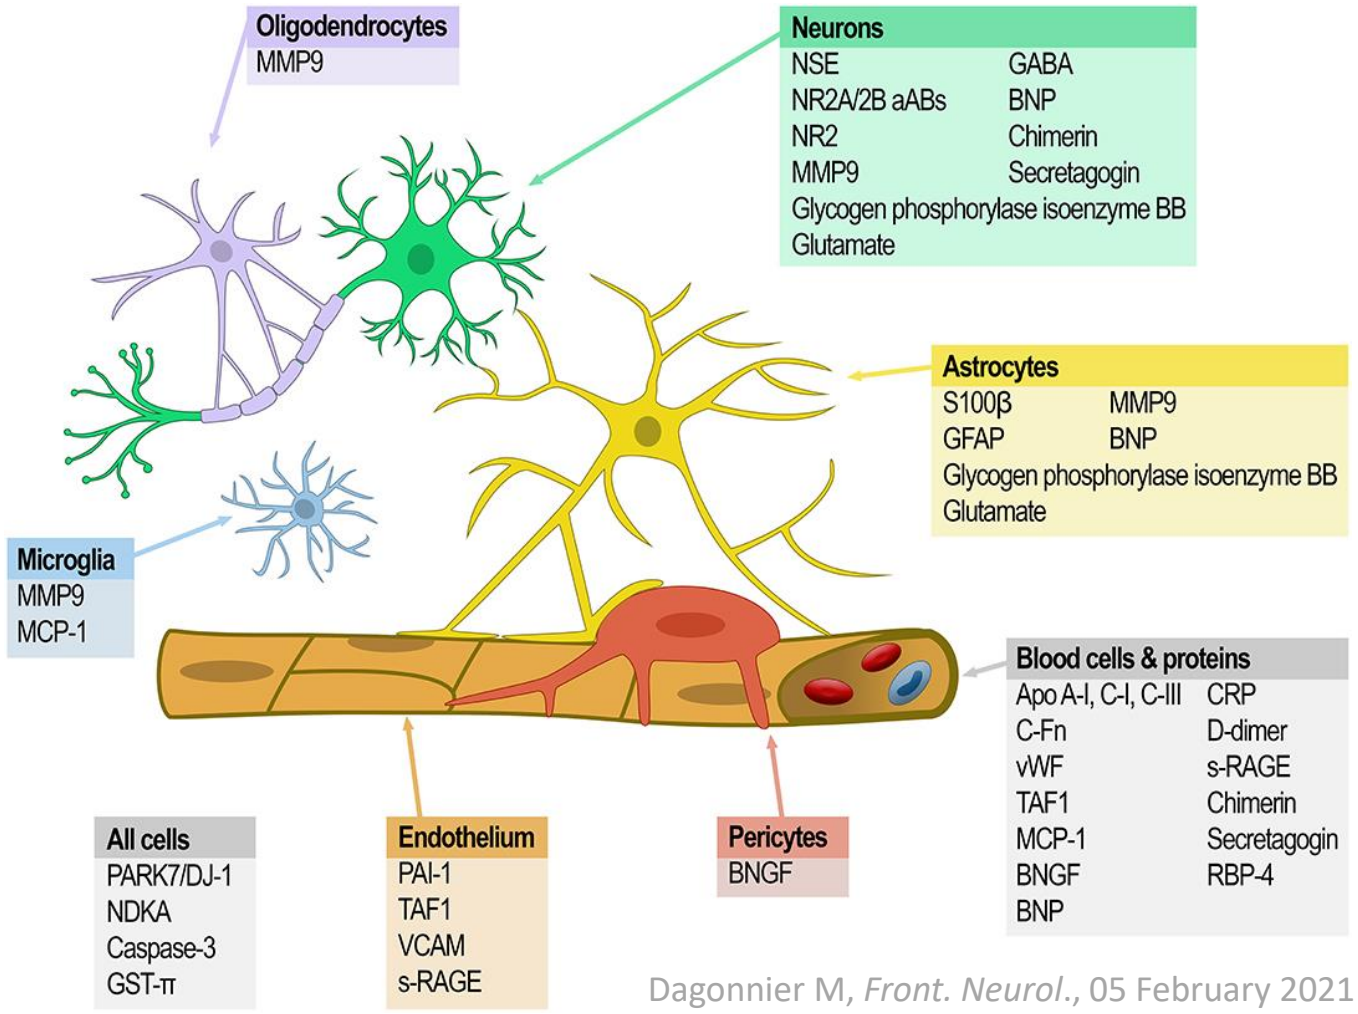
BIOMARKERS FOR IDENTIFICATION OF STROKE AND ITS RECOVERY

Joan Montaner, Anna Rosell

RICORS-ICTUS | Instituto de Salud Carlos III



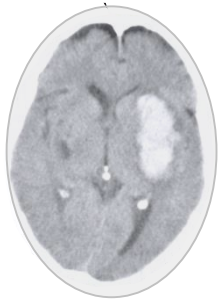
Dagonnier M, *Front. Neurol.*, 05 February 2021

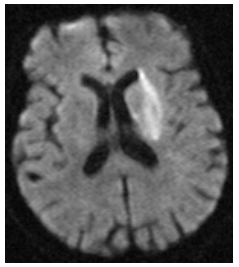
Financiado por la Unión Europea NextGenerationEU

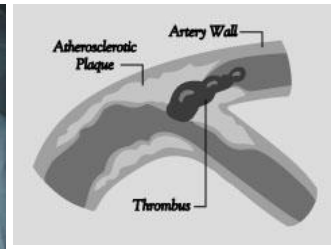
Plan de Recuperación, Transformación y Resiliencia

The PROMISE…

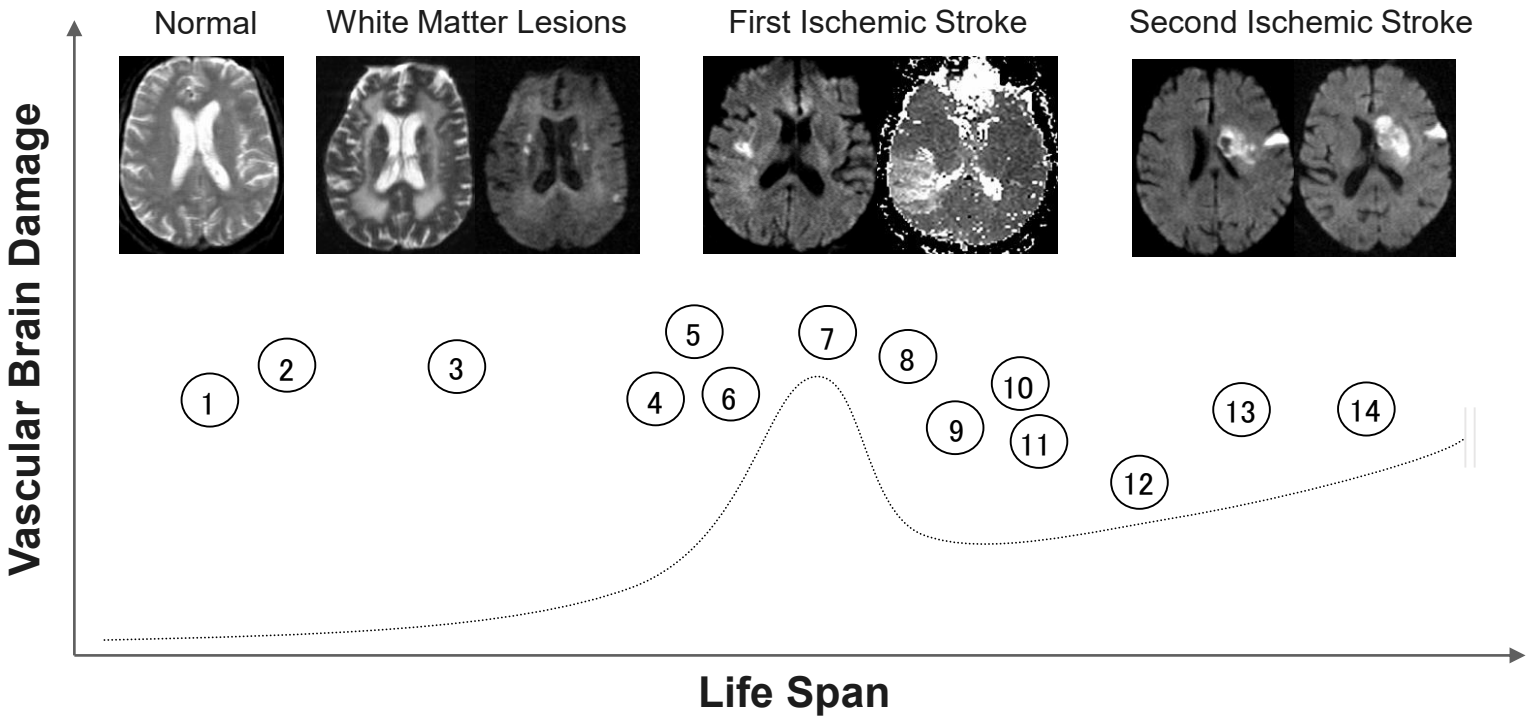
From the ambulance to the out-patients clinic, blood biomarkers based decisions will be taken soon…







Blood Biomarkers & Stroke Natural History



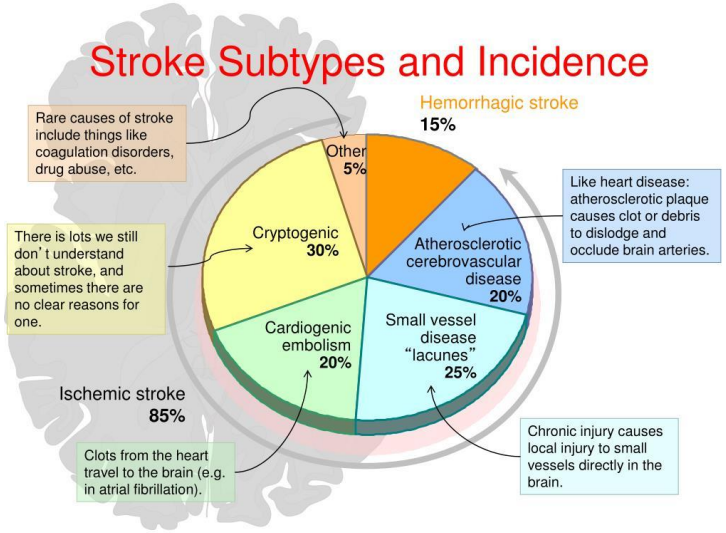
1.– Predict stroke among healthy people
2.– Predict stroke among those with vascular risk factors
3.– Identify Silent strokes
4.– Stroke vs mimics
5.– Ischemic–Hemorrhagic
6.– LVO identification
7.– Bleeding complications
8.– Futile recanalization
9.– Stroke etiology
10.– Cardiac complications
11.– Infections prediction
12.– Functional outcome & recovery
13.– Post–stroke seizures
14.– Stroke recurrence

BIOMARKERS FOR IDENTIFICATION OF STROKE AND ITS RECOVERY

- **WP1:** Biomarkers for the pre-hospital diagnosis of stroke
- **WP2:** Use of biomarkers in stroke subtypes
- **WP3:** Biomarkers for outcome (stroke complications and recovery)
- **WP4:** Biomarkers in experimental models of stroke and selected pathways

WP1: pre-hospital

WP2: stroke subtypes

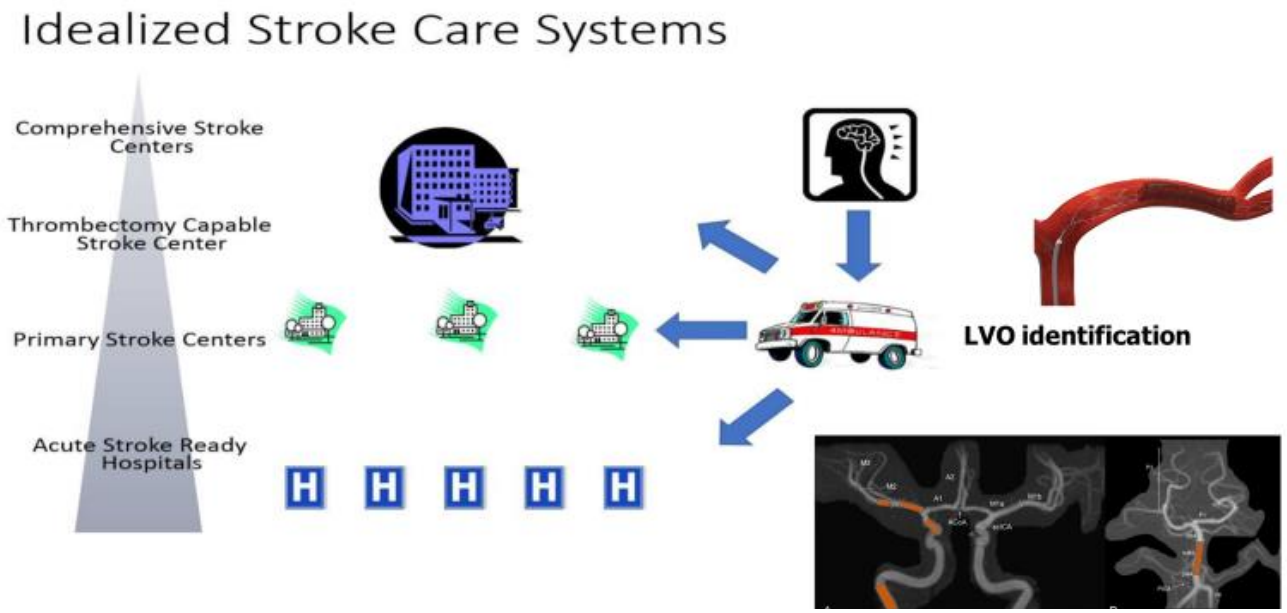


WP3: Outcome

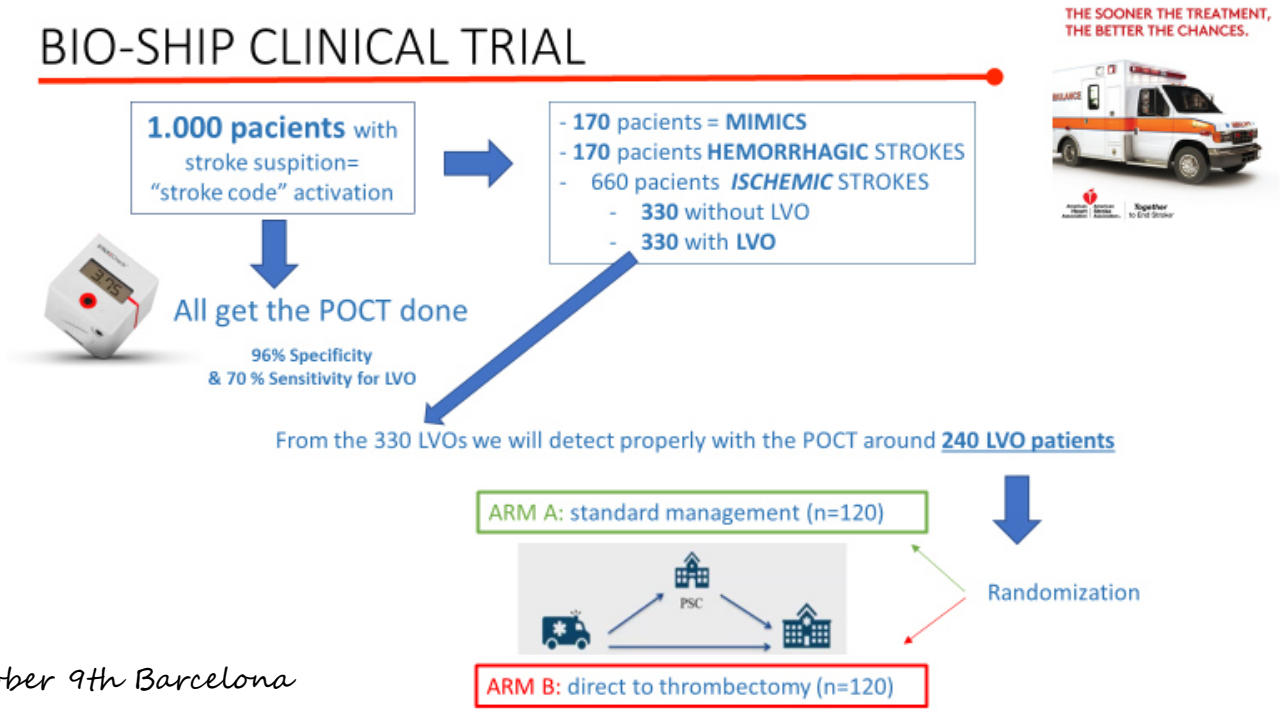
WP4: experimental

WP1.- BIOMARKERS FOR PRE-HOSPITAL DIAGNOSIS OF STROKE. As an alternative to neuroimaging, some blood-based biomarkers identified in the network have shown good predictive ability to discriminate between ischemic and hemorrhagic stroke and to identify large vessel occlusion (LVO) in the ambulances (BIO-FAST, CinicalTrials: NCT04612218). This has generated one of the largest and unique cohorts in the world in which blood samples were obtained at the ambulance that will allow discovery of new biomarkers (n=300) and brings the possibility of starting stroke therapy outside the hospital.

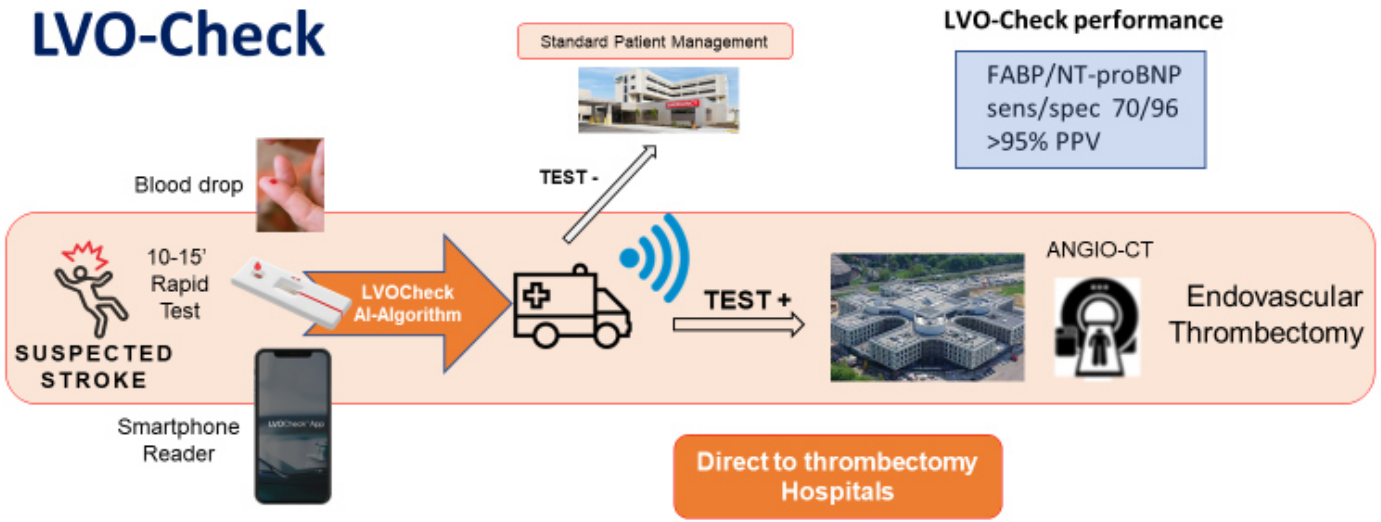
2022



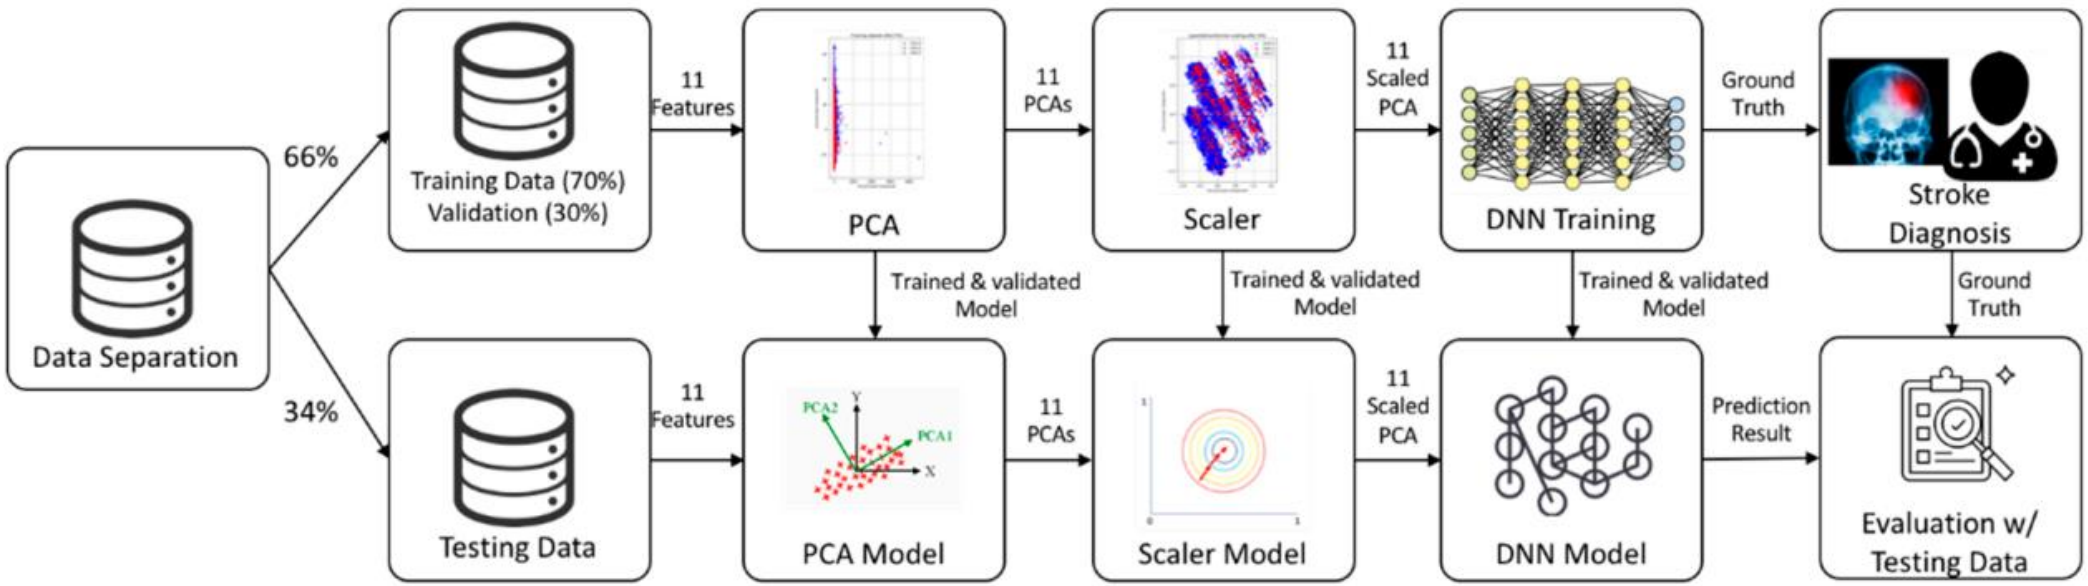
2023



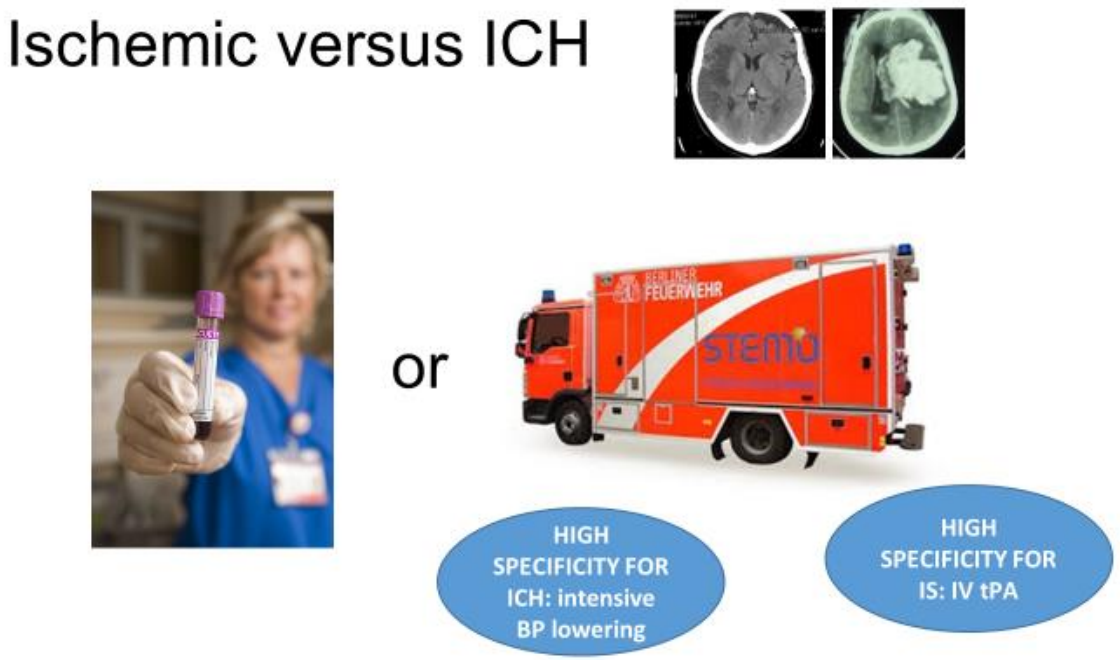
1.- Increase access to reperfusion therapies and thrombectomy centers, by detecting LVO in ambulances using blood biomarkers and clinical scales for direct transfer to the thrombectomy room. This strategy would be novel worldwide since no stroke care network is carried out such type of studies**. A multicenter study in Spain (BIOSHIP-Spain)** will be attempted in the RICORS since we already have the point-of-care technology to make these measurements. In a short time, we could carry out a study to evaluate the impact of the strategy on the prognosis of patients (our hypothesis is that this strategy will improve by 15% the percentage of patients who would achieve functional independence compared to standard managed patients).



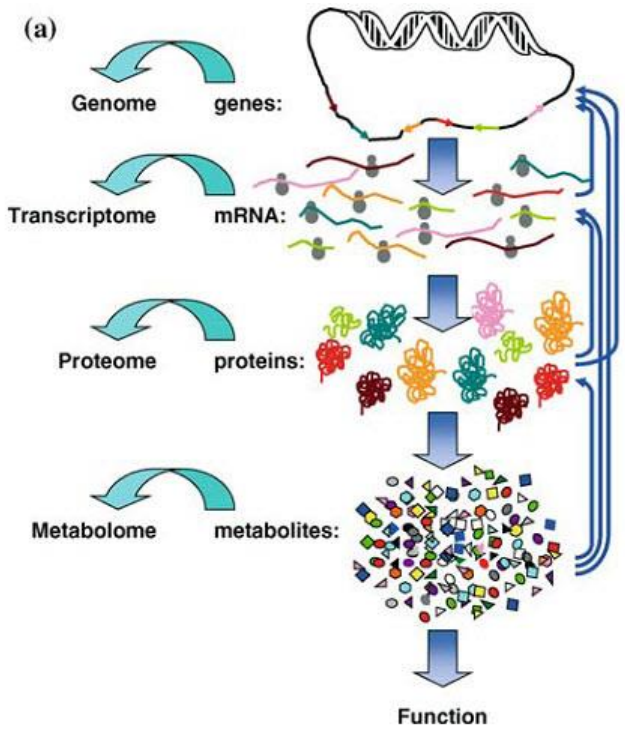
2.- Application of **machine learning techniques** on continuous hemodynamic monitoring data in patients with suspected out-of-hospital stroke and search for plasma biomarkers and clinical scale to generate predictive models of hemorrhagic vs ischemic stroke, and predictive LVO scales

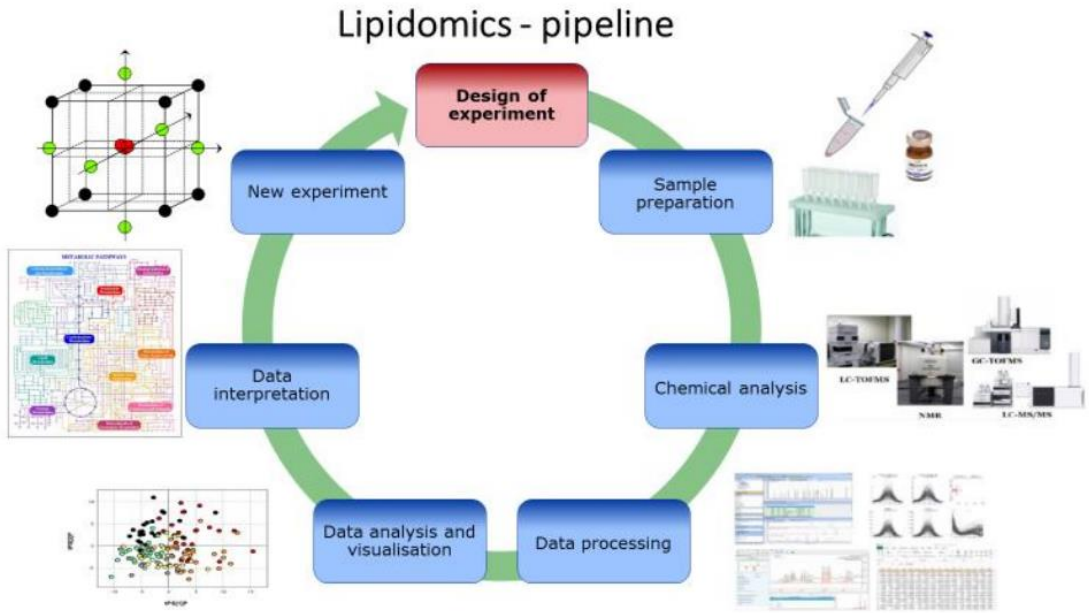


3.- Evaluation of **biomarkers through nasal exudate in stroke.** Preliminary data show metallic biomarkers (iron, copper, zinc, cadmium) in nasal exudate that allowed the differentiation between ischemic and hemorrhagic stroke (García-Cabo et al., Cerebrovasc Dis. 2020). This innovative strategy will be expanded by the network.



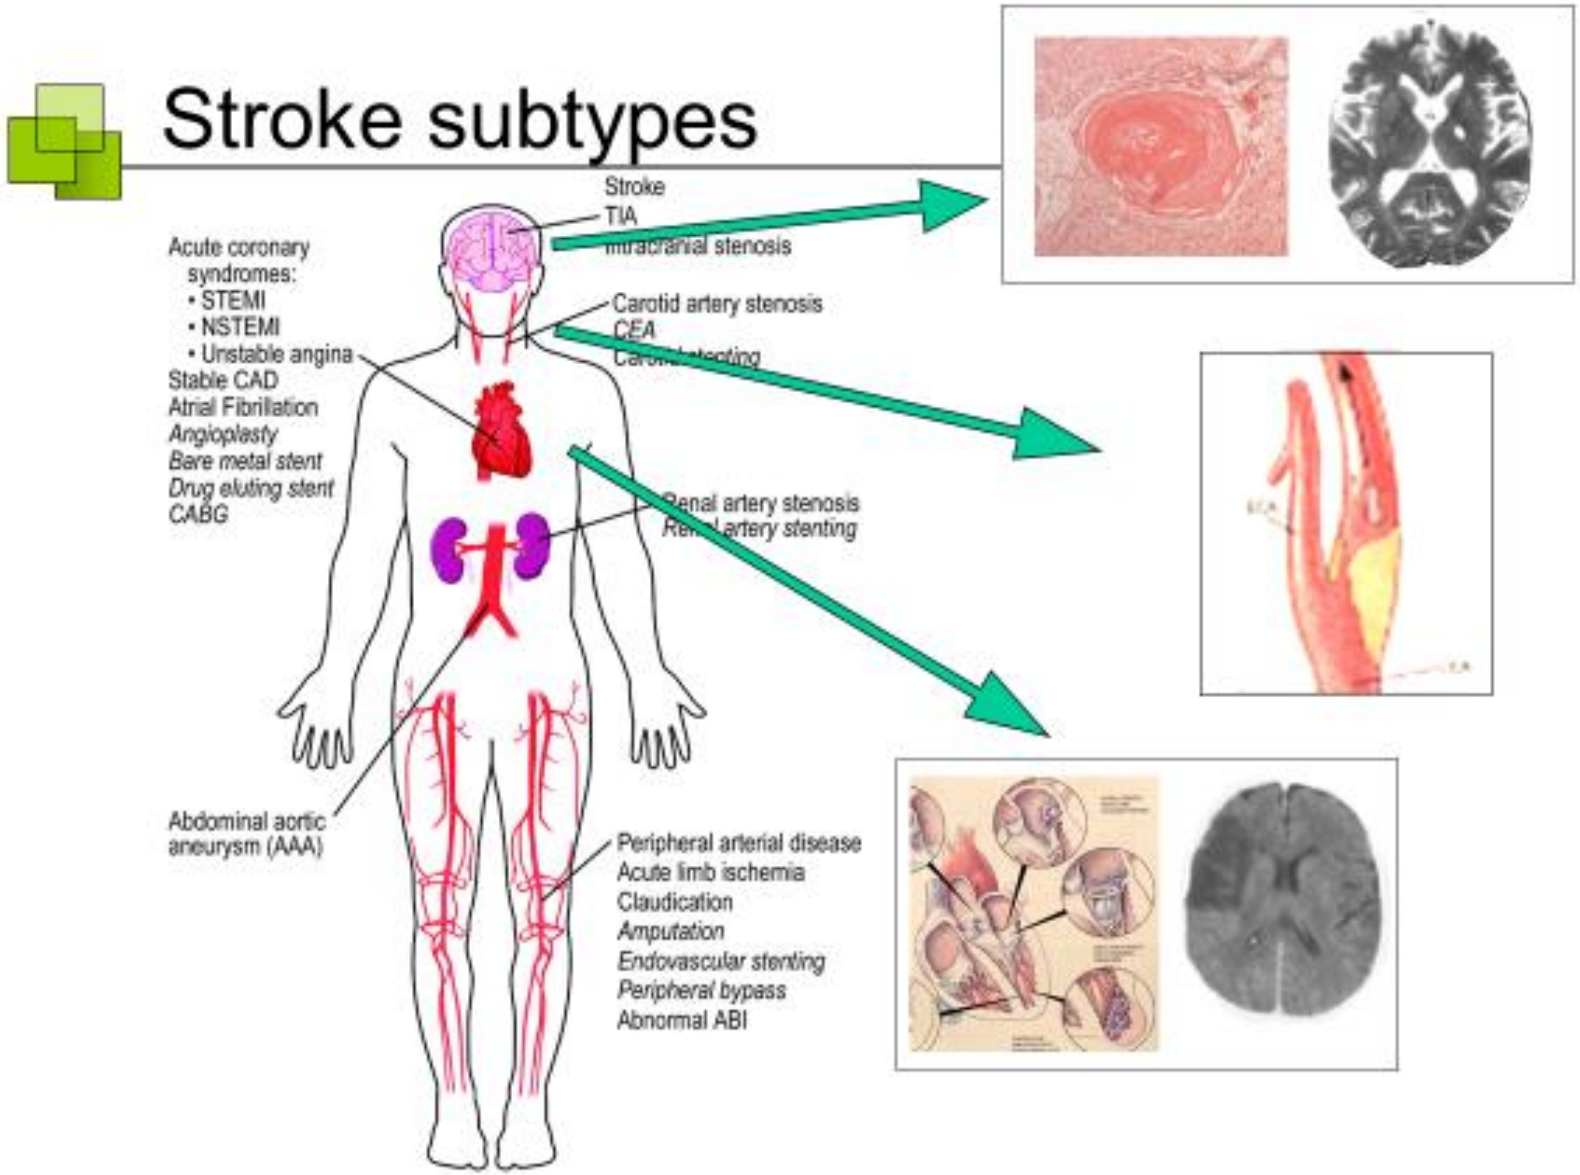
4.- Study of the **metabolomic and lipidomic profile of subjects** with suspected stroke and identification of an omics profile related to a) the certainty of the diagnosis of ischemic stroke, hemorrhagic stroke and mimic b) the presence of intracranial occlusion c) time of evolution of symptoms and the presence of penumbra at risk tissue.



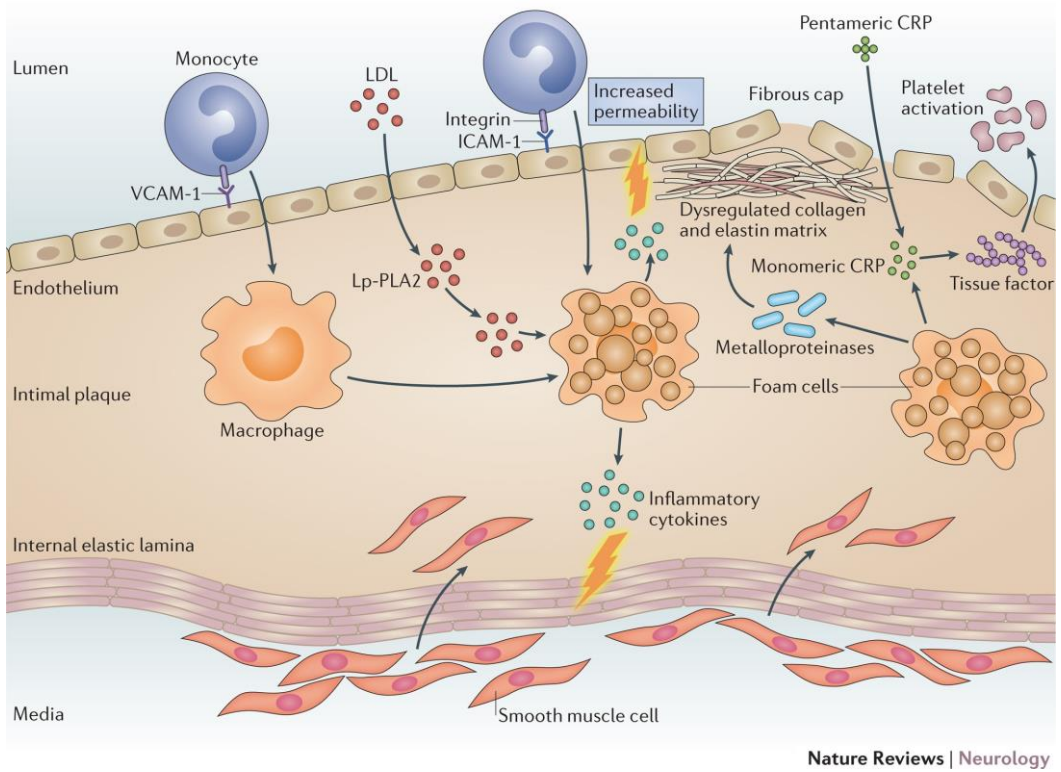


The steps involved in a lipidomic workflow. Adapted from the Swedish Metabolomics Centre (SMC).

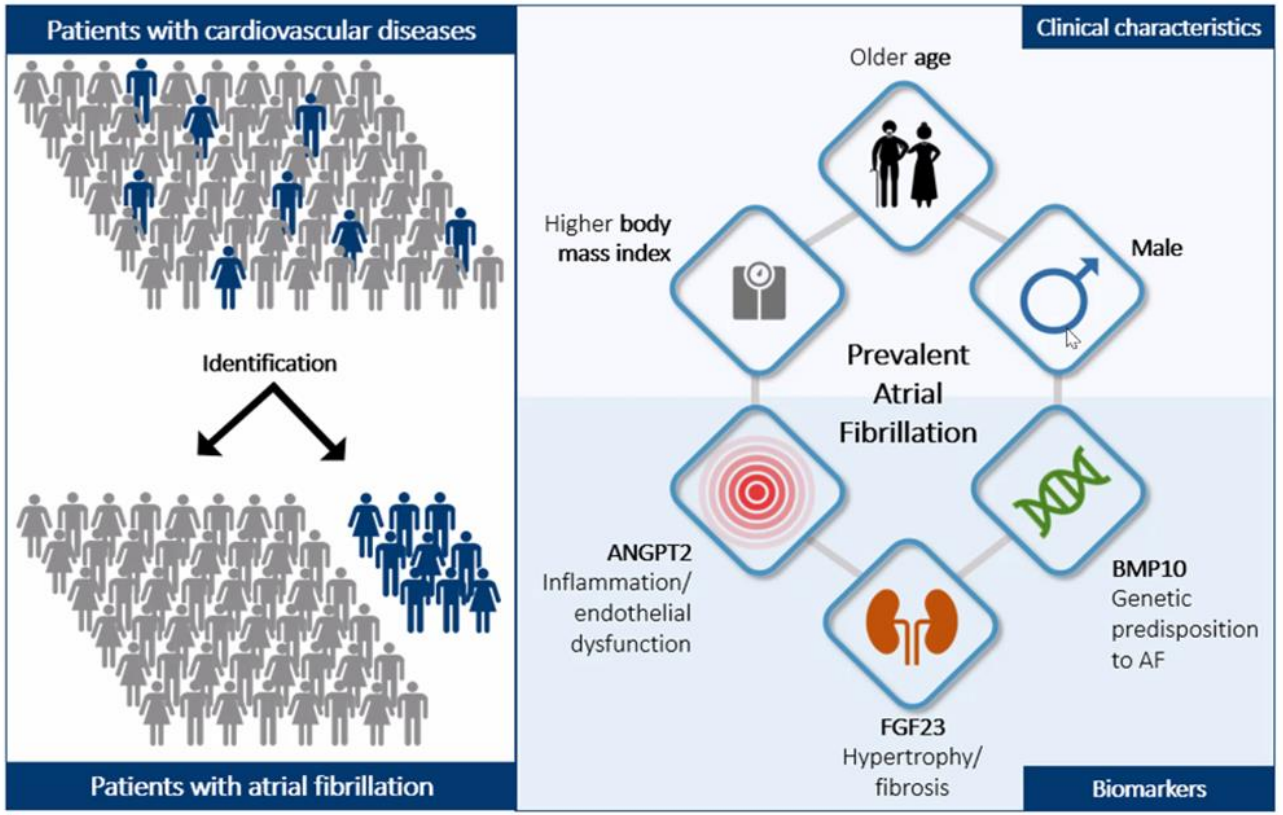
WP2.- USE OF BIOMARKERS IN STROKE SUBTYPES. We will identify new stroke markers to accelerate its diagnosis and therefore improve the treatment and prognosis of patients. Systemic biomarkers of active intracranial atherosclerosis plaque, predictive markers of vulnerable plaque and carotid angioplasty complications. Biomarkers of cardioembolic stroke to develop a predictive model for the presence of atrial fibrillation. Metabolomic, lipidomic, genetic and epigenetic markers of hemorrhagic stroke (ICH and SAH).



1.- To identify systemic biomarkers of **active intracranial atherosclerosis plaque** is an unmet need that will be addressed by the network, as well as predictive biomarkers (proteins and miRNAs) of vulnerable plaque in patients with carotid stenosis through analysis of atheroma plaques and blood (miRNAs) samples from patients with different diagnosis. Among those receiving carotid revascularization, identification of predictors of carotid angioplasty complications with the idea of improving the prognosis of patients who receive angioplasty/carotid stenting using predictive biomarkers of hyper-perfusion syndrome and restenosis, the two most feared complications among those patients, will be also attempted.

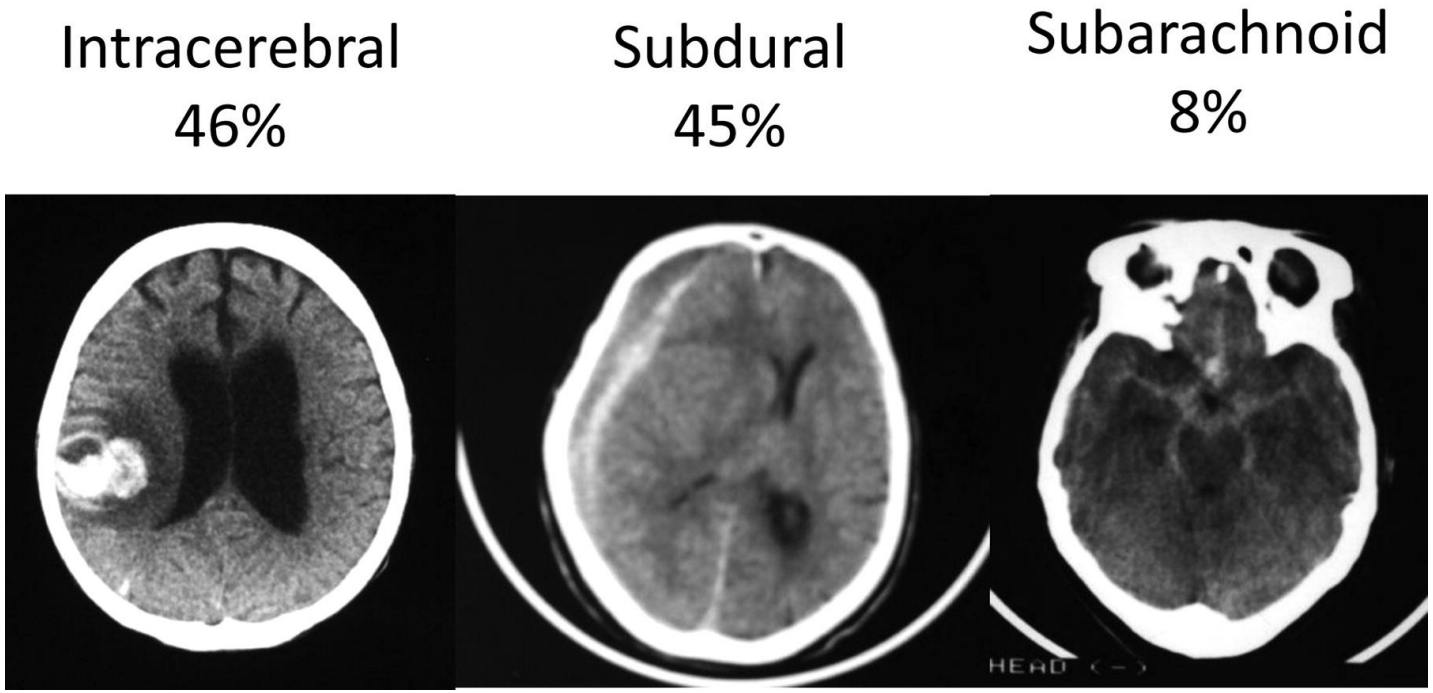


2.- Biomarkers of **cardioembolic stroke**. To develop a predictive model for the presence of atrial fibrillation in patients with recent ischemic stroke, based on clinical, biochemical, echocardiographic and neuroimaging markers, by means of a retrospective cohort study for the development and internal validation of a predictive model for the diagnosis of de novo atrial fibrillation in patients hospitalized for ischemic stroke, as well as the implementation of a screening for atrial fibrillation in patients with stroke of undetermined etiology.

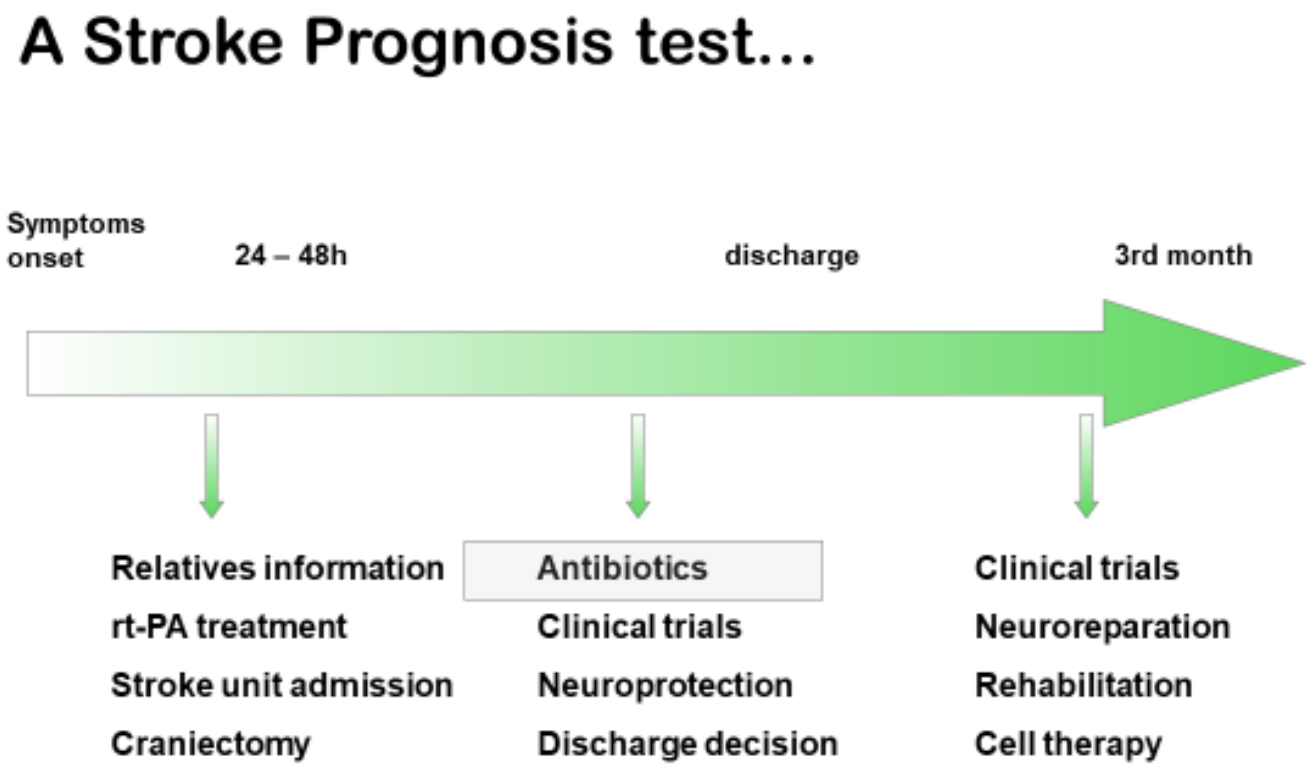


UNIVERSITY OF BIRMINGHAM | INSTITUTE OF CARDIOVASCULAR SCIENCES

3.- **Biomarkers of hemorrhagic stroke.** Study of the metabolomic and lipidomic profile related to the etiology and prognosis of patients with intracranial hemorrhage (ICH). Identification of genetic and epigenetic variants associated with ICH and its functional prognosis (GWAS). Characterization of a CSF biomarker profile in patients with amyloid angiopathy and its validation. We will also address the study of biomarkers in subarachnoidal hemorrhage (SAH), through the study of neuroimaging, blood and CSF biomarkers of early and delayed ischemic damage and functional recovery in spontaneous SAH. That will be complemented by exploring genetic and epigenetic variants associated with SAH and its functional prognosis. (GWAS, EWAS) and analyzing the complications of SAH: by means of a multi-omic analysis.

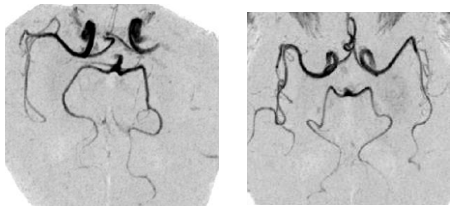


WP3.- BIOMARKERS FOR OUTCOME (STROKE COMPLICATIONS AND RECOVERY). We will study predictive biomarkers of complications associated with reperfusion therapies (HT, futile recanalization) to improve reperfusion rates and benefits/risk balance. We will also study predictive biomarkers of growth of ischemic and hemorrhagic (ICH and SAH) brain injury. The composition of the extracted thrombus and the implication on stroke outcome will be also explored to improve the diagnosis, treatment, and prognosis of those patients. Finally, we will determine different biomarkers related to functional recovery and post-stroke cognitive impairment.

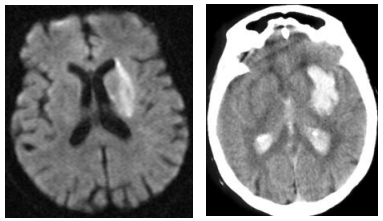


1.- **Lesion growth and tissue viability biomarkers**. Application of machine-learning techniques on continuous hemodynamic monitoring data to generate predictive models of death, re-bleeding and hemorrhagic transformation. Those will be combined with predictive blood biomarkers of complications associated with reperfusion therapies in patients with acute ischemic stroke (AIS). In fact, a great importance will be given to biomarkers of **FUTILE RECANALIZATION**, that importantly limits response to endovascular treatment in AIS (NORDICTUS network). We will try also to identify predictive biomarkers of growth of ischemic and hemorrhagic brain injury. Specifically, analyzing non-coding RNAs and cell-free DNA (cf-DNA) to identify circulating non-coding RNAs (miRNAs, lncRNAs and circRNAs) that predict hematoma growth in patients with ICH. Complementary neuroimaging markers will be also used to analyze whether the brain CT-perfusion (TCP) study increases the sensitivity in the detection of Spot-Sign (SS) and to investigate whether perihematoma hypoperfusion is associated with hematoma growth and its impact on the prognosis of patients (Deep Learning). Some specific pathways (dimetilarginines and other peri-hematoma damage biomarkers) will be explored.

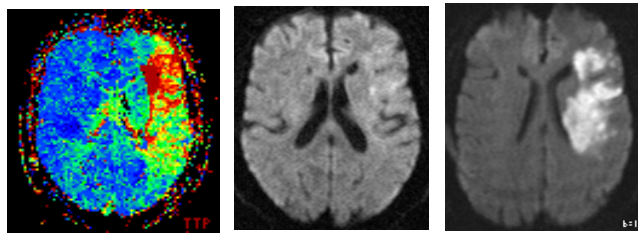
Vessel recanalization



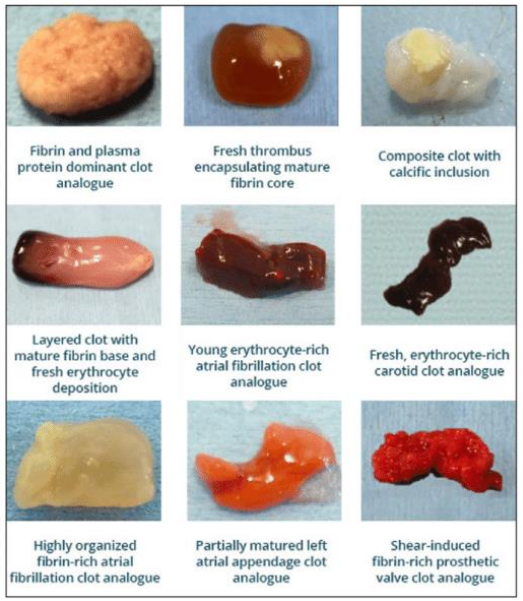
Bleeding Complications

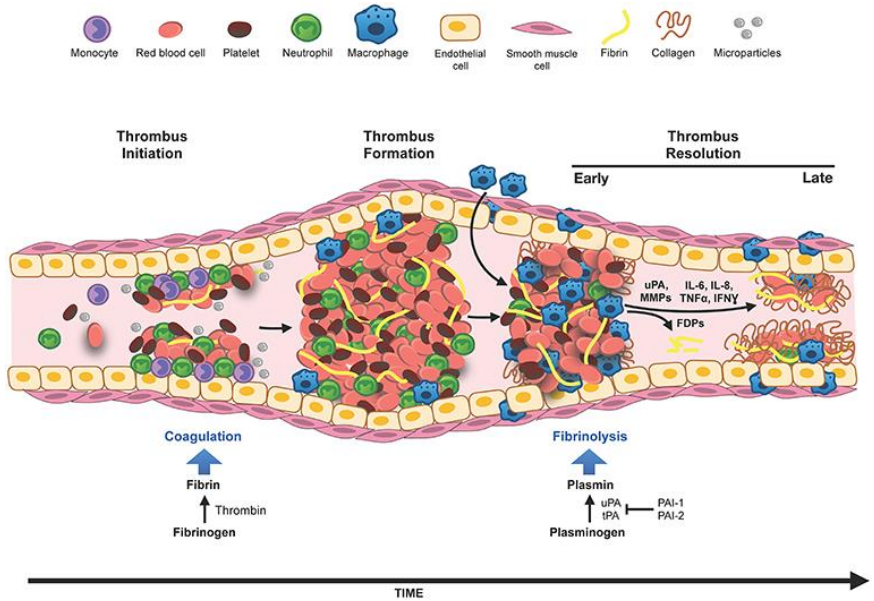


Tissue Viability, biological clock



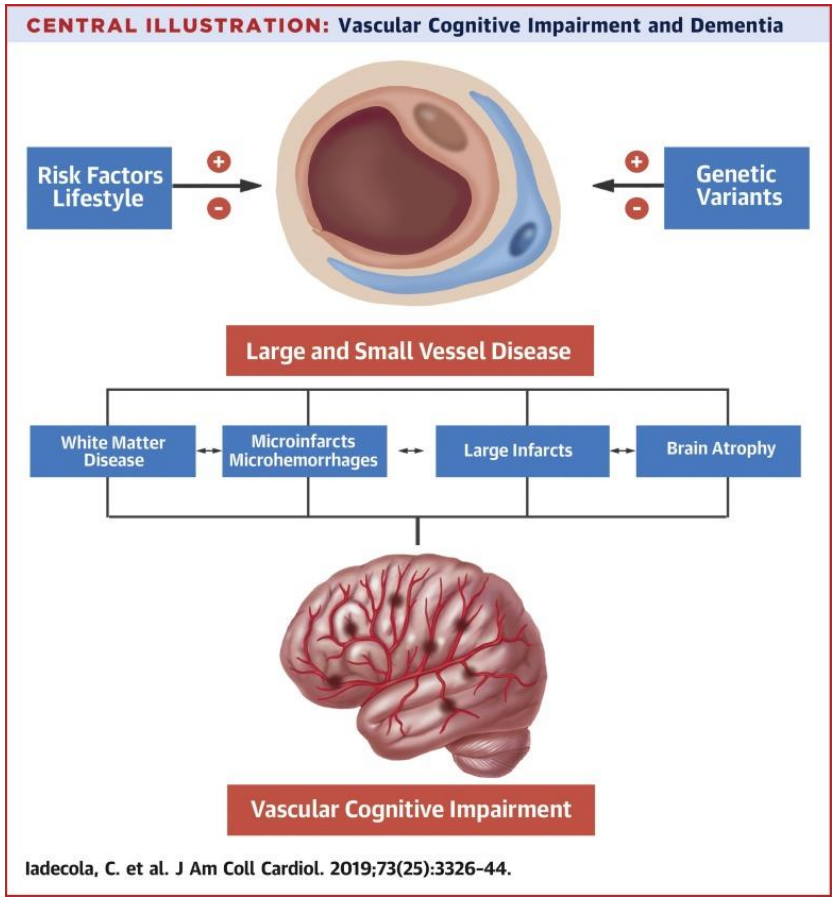
2.- Biomarkers **of the extracted thrombus**. The network will explore associations between macroscopic and radiological images, thrombus composition, blood biomarkers and angiographic/neurofunctional result; attempting the identification of a molecular/cellular signature with diagnostic/prognostic potential. Association of adherence and composition of the Mediterranean diet with the composition of thrombi in patients with AIS treated by mechanical thrombectomy will be explored. Thrombus molecular and cellular level to establish biomarkers of etiology and resistance to recanalization that allow improving their diagnosis, treatment and prognosis of patients will be explored through the study the transcriptome of extracellular vesicles (EVs) from thrombi and plasma samples. Also, redox proteomics applied to the diagnosis of ischemic stroke biomarkers to identify protein biomarkers by proteomic analysis, in thrombi obtained from thrombectomies and peripheral blood.





3.- **Global FUNCTIONAL OUTCOME biomarkers**. In this objective, we intend to identify new predictive biomarkers of brain damage and biomarkers of post-rehabilitation functional recovery, using different lab techniques. This will involve the identification and monitoring of both brain and peripheral markers. Baseline imaging markers predictors of recovery after stroke will be implemented in forecasting algorithms based on AI. Specifically, we intend to identify genetic and epigenetic variants associated with stroke and its functional prognosis. To analyze temporal variation in DNA methylation after a stroke, and its association with its severity and clinical evolution.

4.- **Biomarkers of cognition decline following stroke**. Study of post-stroke cognitive deficit markers by a metabolomic study and neuroimaging in animal models and in patients. Those will be complemented by the study on the value of functional near infrared spectroscopy (fNIRS) as a prognostic biomarker in patients with cerebral infarction and executive dysfunction.



WP 4.- BIOMARKERS IN EXPERIMENTAL MODELS OF STROKE AND SELECTED PATHWAYS FOR DIAGNOSIS AND THERAPY.

The main goal of this WP is to use experimental models to identify new outcome biomarkers and confirm the ones identified in previous WP. Identification of new predictive biomarkers of brain damage and worsening in murine models of cerebral ischemia by comparing those who die/survive at different timepoints after MCAO will bring new candidate biomarkers to the stroke field. We use a dynamic study of cerebral infarction and reperfusion in a humanized model of stroke in pigs through endovascular access, using imaging markers.

Those biomarkers identified in a cohort of stroke patients, corresponding to **functional polymorphisms of genes**, identified as key in experimental studies evaluating the balance between brain damage and repair in murine models of ischemia and hemorrhage will be further explored in vitro and in vivo. Functional studies will be performed in an in vitro model of atherosclerosis to elucidate its role in the progression and instability of atherosclerosis. Functional studies will also be carried out in an in vitro model of ICH to provide information on the role of the identified non-coding RNAs in controlling the expression of their targets and in cell viability and permeability. Proteomic studies to identify biomarkers involved in brain damage and recovery after ischemic stroke, focused on biological sub-compartments, addressing studies limited to known targets and of potential interest. Finally, evaluation of neuroinflammation **biomarkers in preclinical ischemic stroke** will be carried out. Study of brain and peripheral receptors as potential experimental therapeutic targets will be addressed and evaluation of neuroimaging biomarkers for PET/MRI imaging in preclinical ischemic stroke conducted together with the study of brain receptors and lipidomics.

1. BIOMARKERS FOR IDENTIFICATION OF STROKE AND ITS RECOVERY (interim scientific production)

Diagnosis and prognosis in stroke patients is challenging due to the limited accuracy of current models. Biomarkers could enhance diagnostic and prognostic capabilities by providing additional information. The goal is to identify new biomarkers that allow rapid diagnosis and prognosis, improving therapy and patient outcomes.

PREVIOUS RESULTS. The research groups participating in this line have made significant progress with relevant publications in the 4 WPs we explored.

WP1. Biomarkers for the pre-hospital diagnosis**:** for reperfusion therapies (7).

WP2. Use of biomarkers in stroke subtypes: linked to atrial fibrillation, cerebral amyloid angiopathy, intracerebral hemorrhage and transient ischemic attack (8-12).

WP3. Biomarkers for outcome (stroke complications and recovery): Focuses on biomarkers for thrombectomy, futile reperfusion, recurrence prevention and post-stroke epilepsy (13-16).

WP4: Biomarkers in experimental models: such as extracellular vesicles and markers of hemorrhagic transformation (17,18).

Finally, **3 collaborative projects** open to network members are: a) **BIOSHIP** (led by IBIS-Sevilla) was launched with the involvement of several groups within the network and is expected to be completed in the coming years. This study aims to validate the potential use of a rapid Point-of-Care device for the pre-hospital diagnosis of ischemic stroke due to large vessel occlusion, enabling direct transport from the ambulance to thrombectomy centers. It is anticipated that this approach will increase by 15% the percentage of patients who achieve functional independence compared to those managed through standard care; b) MACHINE-Learning: (led by La Princesa-Madrid), focuses on developing predictive models for outcomes like mortality and hemorrhagic transformation; and c) **RACE-PLUS**, (German Trias i Pujol), works on validating the RACE-PLUS algorithm using machine learning to differentiate ischemic stroke subtypes in out-of-hospital patients.

BIOMARCADORES PARA LA IDENTIFICACIÓN DEL ICTUS Y SU RECUPERACIÓN

Nuestro objetivo es identificar nuevos biomarcadores diagnósticos y de pronóstico en el ictus. Los biomarcadores incluirán biomarcadores sanguíneos (genéticos, proteínas, exosomas, miRNAs, etc.) y biomarcadores de imagen. Esta línea de investigación es también una línea transversal a las otras 4 líneas, ya que uno de los objetivos principales es realizar un diagnóstico y pronóstico rápido que tendrá efectos directos en el proceso terapéutico y en la evolución de los pacientes. Esta será una línea de investigación con presencia de todos los grupos de la RICORS. Cuatro paquetes de trabajo:

- WP1: Biomarcadores para el diagnóstico prehospitalario del ictus;
- WP2: Uso de biomarcadores en subtipos de ictus;
- WP3: Biomarcadores para el resultado (complicaciones del ictus y recuperación);
- WP4: Biomarcadores en modelos experimentales de ictus y vías seleccionadas para el diagnóstico y la terapia.

Presentación de la línea.

INTRODUCTION

- Fatty Acid Binding Protein (FABP) and NT-proBNP are brain damage blood biomarkers with prognostic value among stroke patients.
- Almost half of thrombectomy patients suffer futile recanalization but we have NO effective tool or device to forecast those with bad outcome is spite of effective recanalization of the occluded brain vessel.

AIM

- A smartphone APP reading a rapid blood test measuring those biomarkers has been developed to be used at the angio-suite to predict outcome among large vessel occlusion (LVO) patients that receive thrombectomy.

METHOD

- Consecutive patients (n=308) with confirmed LVO and receiving thrombectomy included in the ARTISTA prospective registry were recruited. Blood samples were obtained at thrombectomy, samples were centrifuged, and plasma was biobanked. A rapid POC test measuring both markers at the same time and scanned with a smartphone APP that offered quantitative values of each biomarker was performed. Functional outcome at 3 months was the main endpoint.

DUOCheck test — Reading APP

SCAN the QR code to learn how to perform the test:

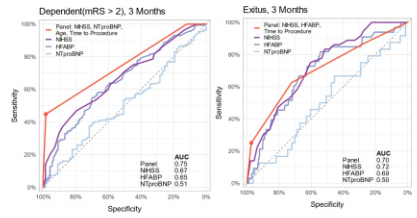
RESULTS

- Following thrombectomy 143 patients (46.4%) remained independent (mRS 0-2) and 37 died (12.1%) at 90 days. Clinical factors significantly associated with poor outcome in multivariate models were age, baseline NIHSS, previous mRS, diabetes and time from symptoms onset to blood sampling. FABP was highly elevated among dependent and deceased patients (p<0.001). Using Panelomix software we identified optimal cutoffs in two panels of biomarkers+clinical parameters to predict outcome with excellent specificity.

Characteristic	mRS=<2, N = 143[1]	mRS>2, N = 165[1]	p-value[2]
Sex (Female)	60 (42%)	83 (50%)	0.14
Age	68 (57, 76)	75 (68, 82)	<0.001
NIHSS Admission	12 (7, 19)	19 (12, 23)	<0.001
Previous mRS			<0.001
0	116 (81%)	88 (54%)	
1	21 (15%)	30 (18%)	
2	6 (4.2%)	23 (14%)	
3	0 (0%)	19 (12%)	
4	0 (0%)	3 (1.8%)	
Wake-Up Stroke	58 (41%)	69 (42%)	0.8
Diabetes Mellitus	43 (30%)	59 (36%)	0.3
Procedure SBP	150 (137, 168)	150 (139, 170)	0.8
Symptoms to Blood Collection Min.	277 (167, 579)	365 (220, 565)	0.10

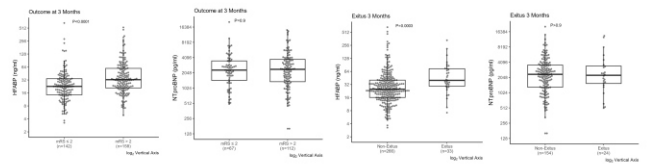
[1] n (%); Median (IQR)

[2] Pearson's Chi-squared test; Wilcoxon rank sum test; Fisher's exact test



3 months mRS>2 prediction: *specificity= 98.3% and sensitivity= 44.8% (panel= NIHSS/FABP/NT-proBNP/age/previous mRS/sampling time)*

3 months mortality prediction: *specificity = 97.3% and sensitivity = 25% (panel= NIHSS/FABP/NT-proBNP/sampling time)*



CONCLUSIONS

- A friendly smartphone device might predict outcome among those patients that get endovascular therapies.
- This might aid in future decisions about limiting endovascular therapies efforts or adding neuroprotectants in those with predicted poor outcome despite successful reperfusion.
- A prospective study using whole blood at the angio-suite is running to confirm these findings.

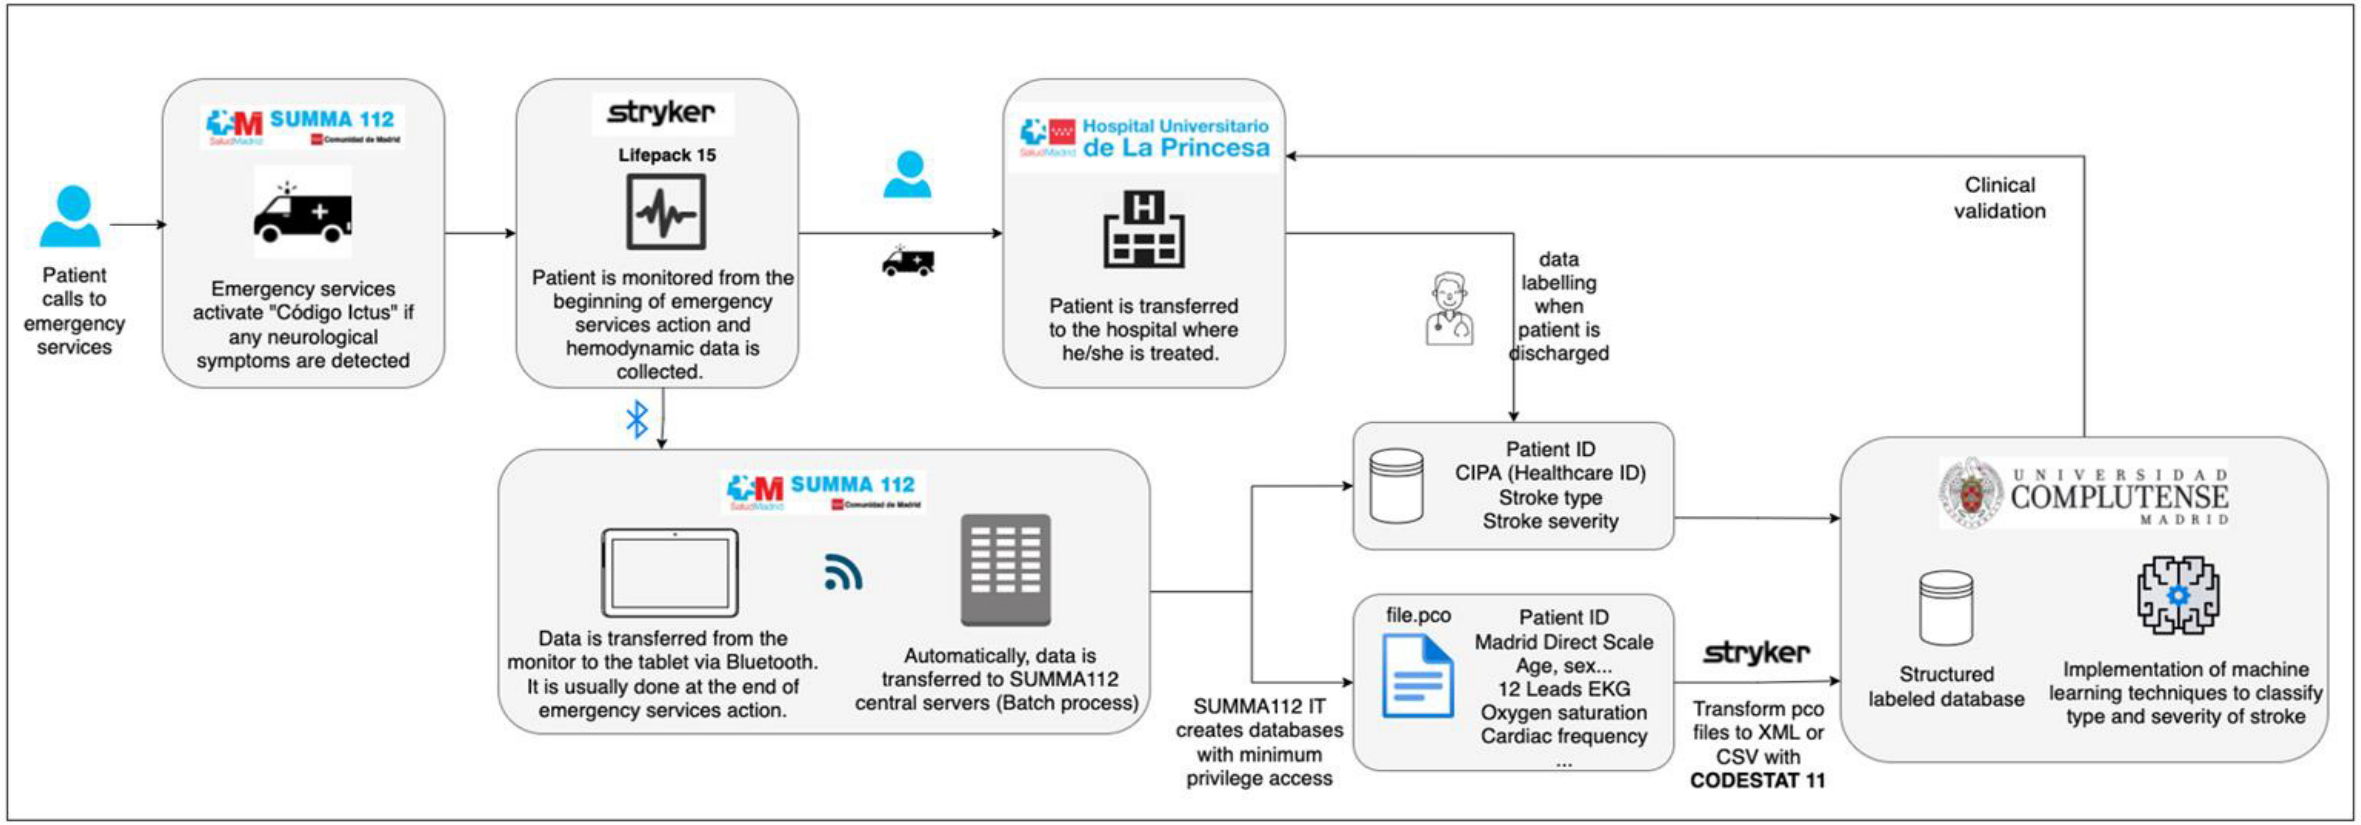
PENDIENTE DE ANALIZAR 2023



RESULTADOS 2022 pendiente de publicación

Modelo de predicción oclusión de gran vaso: F1 score 81% sensibilidad 93% especificidad 65% (KNN)

La información hemodinámica mejora el modelo

- En la fase intrahospitalaria hemos conseguido mejorar y confirmar los modelos de predicción, que están pendientes de presentar en una tesis y de publicar.
- La fase del sistema recomendador está en funcionamiento, en fase de análisis de utilidad y satisfacción mediante una encuesta al personal de la unidad de ictus, para poder hacer mejoras y una posterior implementación a tiempo real en la estación de trabajo de la misma unidad y en dispositivos portátiles.
- De la parte prehospitalaria tenemos ya resultados del 2022 (pendientes de publicar - artículo em fase de redacción). Y vamos a analizar el 2023 (ya etiquetado), pero hay que analizar datos hemodinámicos para confirmar y mejorar modelos de predicción.

Utility of Pro-Adrenomedullin determination in stroke code: The PRESTO Study

IP: José Vivancos. Centro promotor H.U. La Princesa
Responsables: Santiago Trillo y Cristina Sanabria

ABSTRACT:

Introduction:
Proadrenomedullin (Pro-ADM) is a precursor of adrenomedullin, a peptide similar to procalcitonin. Adrenomedullin functions as a vasodilator, with additional effects on immune modulation and metabolism. The utility of pro-adrenomedullin as a biomarker in cerebrovascular diseases is unknown. The objective of PRESTO study (ProadRenomedullin valuE STroke cOde) was to analyze its potential diagnostic and prognostic utility in patients attended as stroke code (SC).

Methods:
A prospective, observational, single-center study was conducted on patients evaluated as SC (May 2023 - April 2024). Serum levels of pro-ADM were analyzed from emergency extractions prior to neuroimaging. Differences in plasma levels between patients with large vessel occlusion (LVO) defined by T-carotid, M1, M2, or basilar artery, and their association with prognosis were evaluated.

Results:
A total of 130 patients were included. The final diagnosis was ischemic stroke (70.7%), intracerebral haemorrhage (13.1%), and stroke mimic (16.2%). Mean pro-ADM levels were 0.7 pmol/L (SD: 0.29). These levels were significantly higher in older patients ($p<0.001$), those with a history of atrial fibrillation ($p=0.006$), those diagnosed with ischemic stroke due to LVO ($p=0.04$), and those with cardioembolic etiology ($p=0.007$). As a prognostic predictor, pro-ADM correlated with NIHSS at discharge ($p<0.001$), mRS at discharge ($p=0.03$), and at 3 months ($p=0.001$). Pro-ADM levels >1.2 were associated with higher rates of LVO ($p=0.048$) and intra-hospital mortality ($p=0.02$).

Conclusions:
PRESTO study suggests that pro-ADM could be an important biomarker in cerebrovascular diseases.
Pro-ADM levels were associated with LVO diagnosis and cardioembolic etiology, potentially being higher in ischemic compared to hemorrhagic stroke. It also showed prognostic potential.

(1)Neurología, (2)Análisis Clínicos, (3)Fundación de Investigación Biomédica. Hospital Universitario de la Princesa. Madrid (Madrid).

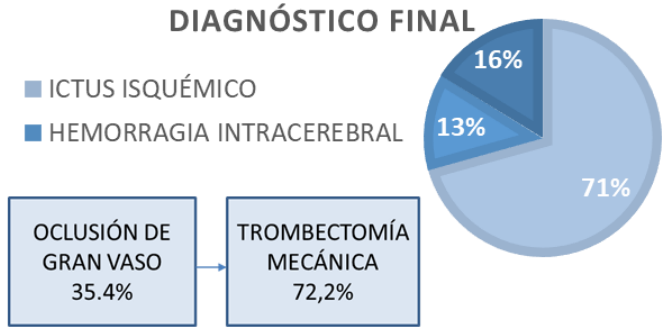
OBJETIVO: analizar su potencial utilidad diagnóstica y pronóstica en pacientes atendidos como código ictus (CI).

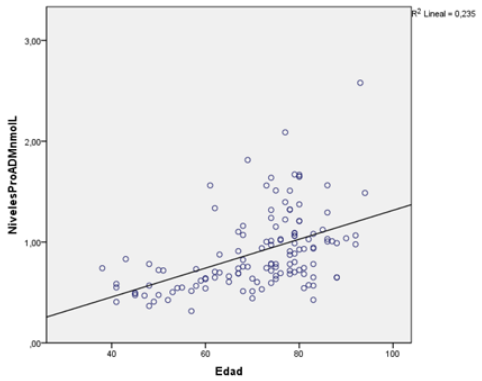
MATERIAL Y MÉTODOS

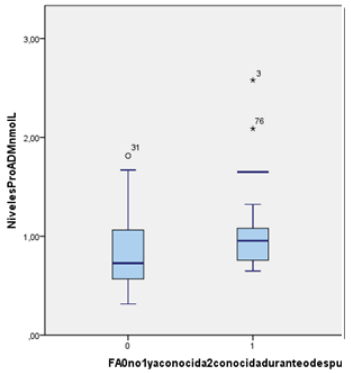
- Estudio observacional prospectivo unicéntrico de pacientes valorados como CI (mayo/23-abril/24).
- Se analizaron los niveles séricos de pro-ADM extraídos de emergencia, previo a la neuroimagen.
- Se evaluaron diferencias en los niveles plasmáticos entre pacientes con oclusión arterial de gran vaso (OGV) definida por T-carotídea, M1, M2, o arteria basilar, y su asociación con el pronóstico.

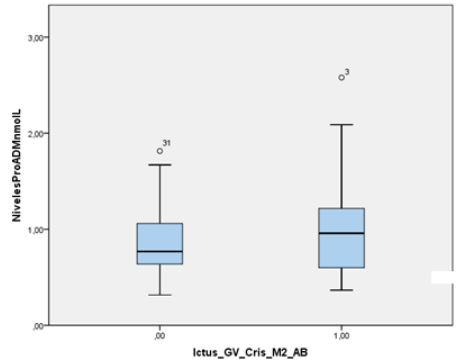
RESULTS

CARACTERÍSTICA	VALOR
Nº de pacientes	130
Sexo (%)	Hombres 60%/Mujeres 40%
Edad media (años)	72 (DE: 13)
NIHSS basal (mediana)	10 (RIC: 4-18)









Niveles de pro-adm significativamente mayores en pacientes con ictus isquemico de etiología cardioembólica: P = 0.007

PRO-ADM y NIHSS ALTA	COEFICIENTE DE CORRELACIÓN (rho): 0,3	P<0,001
PRO-ADM y mrs AL ALTA	COEFICIENTE DE CORRELACIÓN (rho): 0,7	P = 0.003
PRO-ADM y mrs A LOS 3 MESES	COEFICIENTE DE CORRELACIÓN (rho): 0.4	P < 0.001

Pro-adm > 1.2 y OGV	Chi-cuadrado de pearson: 0+04	P = 0.05
Pro-adm >1.2 y muerte intrahositalaria	Chi-cuadrado de pearson 0.01	P = 0,02

Estudio de nuevos biomarcadores en una cohorte de pacientes de vasculitis cerebral primaria:

Nos hemos reunido con 8 grupos de distintos hospitales de la red:
- Hospital de Cruces, Bilbao
- Hospital Virgen de la Arrixaca, Murcia
- Hospital de Donostia, San Sebastián
- Hospital del Mar, Barcelona
- Hospital de Navarra, Pamplona
- Hospital Virgen de la Victoria, Málaga
- Hospital Puerta de HIerro, Madrid
- Hospital Sant Pau, Barcelona

Todos los grupos han mostrado interés en recoger muestras de pacientes con vasculitis cerebral primaria.
El siguiente paso será establecer una serie de criterios de inclusión que deben de cumplir estos pacientes y determinar cuando y qué tipo de muestras se recogerán.
Una vez hayamos puesto en común todos estos criterios, se lo haremos llegar al resto de miembros de la red por si surge algún otro grupo interesado.

Heat map showing the levels of differentially identified proteins in resistant (cortex) and vulnerable (hippocampal CA1) regions, and in control and ischemic samples, in experimental transient global cerebral ischemia. Proteins with asterisk had significant differences compared to their respective control, and may be biomarkers of protection or vulnerability in transient cerebral ischemia.

Identification of proteins in thrombi of cardioembolic and atherothrombotic origin. Color map of the common proteins identified in thrombus samples. Color scale (red/blue) represents their frequency of appearance between cardioembolic and atherothrombotic thrombi. Five and six proteins were found with differences in appearance between both types of thrombi.
